Abstract. In most economies, both developed and developing, industrialisation is viewed as a necessary step towards economic development. New risks for industrialisation are associated with the result of the economic and social changes, regarding the transition to a post-industrial society. Modern progress of organization theory has generated important questions and challenges to conventional sociological and organizational theories. These developments are related to “conditions of postmodernity” – dynamic environment and a post-industrial society with information and knowledge-based nonhomogeneous values as a central research topic. As a result it should be stressed that nowadays society is directly linked to the adjustments in values as a shift to post-industrial modes of production. Modern industrialisation concept should represent the post-industrial society approach, providing framework for the practical applications and explaining the modern company value creation process that corresponds to the economic transformation into post-industrial.

Keywords: industrialisation, post-industrial society, organization theory, performance, ICT, Internet of Things

1. Introduction

Inspecting the origin of the term of industrialisation in Europe, the authors emphasise a major increase of labor productivity due to industrialisation as a significant aspect of the production process. Industrialisation gave a huge advantage over other methods of production and led to the overall development of modern Europe. When considering industrialisation as a contribution to society development, economists point that “towns and cloth manufacturing obviously existed in Western Europe before the eleventh (11th) century, but the advance in economic productivity was underlined as critical, by using better-qualified workers and by increased artisan creativity, substantial improvements in quality and value of the goods produced per working hour input were realised” (Van Der Wee 1975). The aim of the research is to develop the model of modern industrialisation development into post-industrial economy. The starting point for industrialisation the authors define in the process of technical modernisation. Schumpeter, affirms: ‘Inspecting the birth of the modern concept of industrialisation, it is worth noting the process of modernisation’ […] ‘a degree of modernisation can, and
sometimes does, occur without industrialisation, but industrialisation is usually a basic aspect of modernisation’ (Schumpeter 1934). Industrialisation is the totality of relations involving workers, employers and society as they develop to make use of the new machines, processes and services that modern technology has made possible. Industrialisation is usually described by new and more diverse skills, larger-scale productive endeavours, more large cities and much else (Kerr et.al.1960).

2. Industrialisation and management theory development

Discussing the contribution of industrialisation in the efficiency of production process, J. Schmiechein also describes industrialisation as a method of centralising resources of the enterprise in order to improve productivity. He also points out the productivity as the fundamental aspects and the basis of industrialisation. The essence of industrialisation ‘the dominant tendency to centralize production and labour within the factory’ and ‘natural progression to greater and more sophisticated economic organisation […] and greater organisation of labour […] new machinery and dramatic technological innovation’… ‘Accepted patterns of industrial evolution could be explained by changes in technology, supply of labour, consumer demand, or even urban growth’ […]. Fundamental basis for the fast evolution of the productivity theories was established by F. Taylor. Economist Daniel (1992) in his study also indicates that the concept of industrialisation revealed great opportunities and changed its development owing to the research F. Taylor: ‘The study of scientific management provides an avenue for understanding the […] interest in economic and technical rationalisation as well as the evolution of production management and the changing character of industrial work in the middle decades of the century’ (Schmiechein 1975).

Nowadays, the variety of economic theories offer a huge number of different ways to achieve efficient use of company resources. The following Table 1 is representing the major schools of economic history. The authors underline that industrialisation in its core is also sharing the same concept - to improve the resource management efficiency through the development of technical rationalisation and efficient organisational structure. Kuhn also explains that the new research and standards usually include the basics and concepts of the most famous scientific papers, often complementing and developing them: ‘When new paradigm is born from old one; it incorporates much of the vocabulary and apparatus that the traditional paradigm had previously employed, though these elements are employed in different ways’ (Daniel 1992). The authors summarize that subsequent management theories (discussed below) have embraced the idea inherent to F. Taylor, they are proposing to improve the resource management (utility of resources) through the development of the organisational structure or optimisation of the production process efficiency using divergent approaches. The authors stress that owing to above mentioned impulse the structure of the organisation has historically been associated with the production process in order to support its functions. The production process and the structure are closely related and complement each other. Process-based companies have become fashionable during recent years. They are a powerful answer to the problems that functional and product-oriented structured companies faced (Vanherbeke and Torremans 1998).

<table>
<thead>
<tr>
<th>Theory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Org. theory prior to 1900</td>
<td>Emphasised the division of labor and the importance of machinery to facilitate labor.</td>
</tr>
<tr>
<td>Scientific management</td>
<td>Described management as a science with employers having specific but different responsibilities; encouraged the scientific selection, training, and development of workers and the equal division of work between workers and management.</td>
</tr>
<tr>
<td>Classical school</td>
<td>Listed the duties of a manager as planning, organizing, commanding employees, coordinating activities, and controlling performance; basic principles called for specialisation of work, unity of command, scalar chain of command, and coordination of activities.</td>
</tr>
<tr>
<td>Human relations</td>
<td>Focused on the importance of the attitudes and feelings of workers; informal roles and norms influenced performance.</td>
</tr>
<tr>
<td>Classical school revisited</td>
<td>Re-emphasised the classical principles.</td>
</tr>
<tr>
<td>Group dynamics</td>
<td>Encouraged individual participation in decision-making; noted the impact of work group on performance.</td>
</tr>
<tr>
<td>Bureaucracy</td>
<td>Emphasised order, system, rationality, uniformity, and consistency in management; lead to equitable treatment for all employees by management.</td>
</tr>
<tr>
<td>Leadership</td>
<td>Stressed the importance of groups having both social task leaders; differentiated between Theory X and Y management.</td>
</tr>
</tbody>
</table>
### Decision theory (1960s)
Suggested that individuals "satisfice" when they make decisions.

### Sociotechnical school (1960s)
Called for considering technology and work groups when understanding a work system.

### Environmental and technological systems (1960s)
Described the existence of mechanistic and organic structures and stated their effectiveness with specific types of environmental conditions and technological types.

### Systems theory (1970s)
Represented organisations as open systems with inputs, transformations, outputs, and feedback; systems strive for equilibrium and experience equifinality.

### Contingency theory (1980s)
Emphasised the fit between organisation processes and characteristics of the situation; called for fitting the organisation’s structure to various contingencies.

Source: Fligstein 2001

All the modern management theories of the organisation as well as industrialisation concept have structure as the cornerstone to ensure a more efficient production process (See classical theory to 1900, e.g. 1776 A.Smith (Wealth of Nations), and F.Taylor (1911), A.Fayol (1949) until neoclassical works Mayo (1933) and McGregor (1960) Figure 1).

Organisation theory has been developed to describe, explain and predict the functioning of organisations in order to improve their effectiveness and efficiency. Even in modern conditions, the organisation’s strategy includes the efficiency of the production process as a major competitive advantage in the market, and modern scientific works continue to explore methods of creating the optimal structure to ensure the specific processes within the company.

It can be summarised by saying that modern industrialisation has core methods of improving productivity through centralisation of resources, organisation of labor, optimizing company structure, technological innovation, and modern methods of mechanisation of the production process.

### 3. Industrialisation and modern society

In order to fully analyse and create a picture of changes and development of the industrial economy towards modern society, it is necessary to follow the changes in the concept of industrialisation: management of production processes and the main directions of research in this field. Industrialisation played a central dynamic force at work around the world, which includes political and cultural developments as well. The first
industrialisation footprints could be traced back to Maya Age, “Machine Age Maya” (Whyte, 1959). The most significant event in the development of the world economy through industrialisation is considered to be the First Industrial Revolution (hereinafter FIR). Industrial Revolution has dramatically changed the structure of the world economy, and served as fundamental basis for transforming to its present form. Industrialisation has become the primary incentive for the rapid economic development of the numerous countries. It is crucial to understand the factors which played significant role for industrial process development. Industrialisation at that time was an attempt to use more effective methods of production through mechanisation, the division and the special organisation of labor (see Table 2).

After significant technology breakthrough during the 1st Industrial Revolution, the 2nd Industrial Revolution (hereinafter SIR) underlines concentration of capital. Many economists differently explain the incredible achievements of SIR. Higher “capital-labor ratio” or capital density is also considered one of the elements that improve productivity, and due to the fact that capital and labor are mutual substitutes, increasing either capital or labor can raise productivity (Moomaw 1983). Broad number of studies has identified industrial structure, capital density, technology adjustment capacity, labor quality, and agglomeration economies to exist among the main factors affecting urban productivity (Moomaw 1983; Williams and Moomaw 1989; Chandler 1966). Both industrialisation major factors are categorised in Table 3.

The Third Industrial Revolution (hereinafter TIR) began in the last half of the 1950s, with the sudden explosion of U.S. corporations beyond national and continental limits, (Hazen 1969) placed emphasis on more sophisticated cooperation between government and industrial structure. During the TIR, the development of industrial clusters led to new forms of interaction, not only among companies, but also between government and industrial structure. Large industries have accessibility to more extensive and cheaper financial and informational resources, and are more efficient in controlling and their existence is threatened less.

In economics, there is a new appeared concept - industrial cluster or agglomeration. The term ‘industrial cluster’ refers to the company and institutions in close proximity to each other in a particular field and area maintaining an interactive relationship, influencing and supporting each other. Industrial districts innovative performance is correlated to its specialisation, the existence of suppliers, and social and business networks.

Production specialisation, network organisation, trust relations, collective learning, circulation of knowledge and technologies, diffuse entrepreneurship, spirit of emulation, quality, flexibility and mobility of human resources, education, strong domestic competition, and co-penetration between the economy and society in local cultures founded on centuries-long traditions.

The global reorganisation of manufacturing, which is referred to as the new international division of labor, is considered by some to be the defining characteristic of the latest wave of globalisation. Economic exchanges between relatively independent parties have been replaced by complex and highly interdependent systems of industrial production and economic exchange organised on a global scale.

Multinational development

Transition from a “traditional” (rural, backward, agricultural) society to a “modern” (urban, industrial) society directly links the concept of development with industrialisation theory.

Economic growth strategies were emphasised on similarities and dissimilarities in the attitudes taken toward participation in the international division of labor.

Countries that have reached this stage have been alternatively described as “semi-industrial” or “newly industrialised”.

The structural transformation as part of development strategy for developing countries with industrial development as a core idea. Associated with state assistance for declining industries in developing country which could not compete.

Industrial development associated with a supposed ‘imperative’ towards innovation. Innovation takes place in terms both of product improvement and of process design.

Source: the authors presented major factor groups based on Keeble, 1989; W. Koh et al. 2005; Mowery and Teece 1993; Kurth 1979 and etc.

4. Industrialisation and post-industrial society

Modernisation theorists argued industrialisation impact that created modern economies. In the later stages of economic development, ‘the demand for manufacturing also decreases while the demand for services increases’ (Levy 1966). This shifts employment from manufacturing to services. Analysis on postmodern based on Table 5 shows the dramatic changes from industrial to post-industrial modes of production. The authors’s goal is to integrate post-industrial realities into modern industrialisation concept, representing the new economic paradigm in the modern concept of industrialisation. The authors point that, in order to be successful in nowadays markets these tendencies bring us towards the understanding that modern industrialisation concept lacks postindustrial society context analysis (detailed info on Postindustrial society is described in Table 5).

<p>| Table 5. Comparison of the characteristics of the industrial and information (post-industrial) society |
|--------------------------------------------|---------------------------------------------|
| <strong>Industrial society</strong> | <strong>Information society (Postindustrial)</strong> |
| Core | Steam engine (power) | Computer (memory, computation, control) |
| Basic function | Replacement, amplification of physical labour | Replacement, amplification of mental labour |

As a result, nowadays performance depends not only on the production processes; therefore, new performance expressions are considered both on strategic level and decision levels (strategic, tactical and operational). Thus, knowledge in performance expressions of the modern company must be considered from top to bottom for all the activities or processes to be controlled (Bititci 1995; Rangone 1996; Ghalayini et al. 1997; Suwignjo *et al.* 2000). In the information age, effective use of intellectual capital is the most important factor in the success or failure of a business (Goh 2005). Scientists (Eustace 2001; Upton 2001; Lev 2000; Beattie and Pratt 2001; Ignatavičius *et al.* 2015; Tvronavičienė *et. al.* 2015; Travkina, Tvronavičienė 2015; Tvronavičienė, Černevičiūtė 2015; Rezk *et. al.* 2015) have confirmed that demand for knowledge-based resources is growing as companies increasingly base their competitive strength in the value of know-how, patents, skilled employees and other intangibles. The advance of modern Information Communication Technologies (ICT) has launched the Industry 4.0, which is the German newest strategic initiative to take up a leader role in industrial IT which is currently revolutionizing the manufacturing engineering sector (Beattie and Pratt, 2001). Industry 4.0’s strategy will allow to stay a globally competitive with the industrialisation factors discussed from the first, second and third industrial revolution. Technology breakthrough allowed to increase the level of automation and production and labor cost decreased. Commentators use the term “industry 4.0” to refer to a fourth industrial revolution with four main characteristics (Industrie 4.0., 2014) The fourth industrial revolution is more focused on intangible assets (associated with IC) managing company data flow, plant-specific software and the “hardware” of manufacturing technology (industrialisation factors). Since ICT is only one part of the Industry 4.0, the other is its use of industrialisation factors and the utilisation of the benefits that it brings to the value chain (Figure 2). “Industry 4.0” (sometime referred as Smart industry) advantages are coming from the technological evolution - from embedded systems to cyber-physical systems (Figure 2).

![Figure 2. The evolution of embedded systems into the Internet of things, data and services](Source: Acatech 2012)

Cyber-physical systems intelligence helps create intelligent object networking and independent process management, with the interaction of the real and virtual worlds representing a significant new aspect of the manufacturing and production process integration. Industry 4.0 creates networked production, in which orders managed automatically throughout entire value chains, order processing machines and material and organize their delivery to the customer (Schlick, Stephan and Zühlke 2012). Cyber-physical systems provide the basis for using these data efficiently. This is a considerable competitive advantage (reducing downtimes, accurate planning, reducing unit costs and etc.) - the creation of an Internet of Things, which combines with the Internet of Services to make Industry 4.0 symbiosis possible. After considering the main events and stages of development of industrialisation, the authors make the system of industrial production in order to recognize

**Figure 3. Evolution of industrialisation system and industrialisation factors**

*Source: the authors’s presented model using Berger 2014; Helfgott 1986 … etc.*

The authors, based on above-mentioned numerous studies, suggests his own development model of industrialisation factors. By the authors’ opinion – “superimposing” is the most appropriate method to integrate industrialisation factors into post-industrial society. Nowadays, in post-industrial society paradigm traditional manufacturing industry is digitally transformed by exponentially growing technologies (e.g. intelligent robots, autonomous drones, sensors, 3D printing). Manufacturing companies and their industrial processes are adapting to the adjustments in values. The digital computer in the 1950s and the integrated circuit in the 1970s were two inventions that steered the manufacturing technology onto a new shift. Before, only the material-processing system was improved. With the computer age, industrialisation was “superimposed” to the information-processing system in the rationalisation and improvement work. While the mechanisation is best suited for large-scale production, the information-processing system can in general be applied to all manufacturing activities. With the help of the information-processing system machines were equipped with digital control units, systems started to be integrated with each other by a central computer (Hoppe and Berv 1967).

New microelectronic components, especially the microprocessor, came and formed the basis of the powerful and cost-effective control systems of today (Karlsson 1991). These trends started with a greater level of production automation, a process that has, since the 1970s, been driven by developments in electronics and information technology. Computer-aided design (CAD), robots, numerical control (NC) machine tools,
flexible manufacturing systems (FMS), and other programmable automation equipment and systems are supplied by industries that are currently more or less separate. Numerical control (NC) is the oldest and largest, dating from the 1950’s (Hunt 1983). While significant markets for CAD and robots did not emerge until the 1970’s (Kurlak 1982). In the early 1980s industrial robots were seen as the ultimate solution to automatized factories. The productivity also relies on many factors that interact with each other, and therefore ‘the robots alone cannot improve the productivity, a robot is the ultimate mechatronic system’ (Westerlund 2000). New industrial development have increasingly embraced modern ICT, manufacturing industry around the world now integrates ICT creating new approaches to development, production and the entire logistics chain.

Links to both business and social networks – the business web and the social web play an important role in the digital transformation to industry 4.0. Smart network of machines, properties, ICT systems, smart products and individuals across the entire value chain and the full product life cycle establish new environment (Figure 4). Smart Factories continually share information about current stock levels, problems or faults, and changes in orders or demand levels. The widespread adoption by manufacturing industry and traditional production operations of ICT is increasingly blurring the boundaries (Spong, Hutchinson and Vidyasagar, 2006) between the real world and the virtual world in what are known as cyber-physical production systems (CPPSs). Processes and deadlines are coordinated with the aim of boosting efficiency and optimising throughput times, capacity utilisation and quality in development, production, marketing and purchasing. CPPSs not only network machines with each other, they also create a new environment (Figure 4).

![Figure 4. The industry 4.0 environment](image)

*Source: D. Schatsky 2013; DFKI 2013*

Industry 4.0 cornerstone is its interface with other smart infrastructures (e.g. smartmobility, the smart grid, smart logistics and smart homes and buildings). All these new networks and interfaces offered by industry 4.0 within an ‘internet of things, services, data and people’ mean that manufacturing is set to implement considerable changes in future. Traditional industrial society expected to implement this fourth industrial revolution, increasing global competitiveness. This means that industrial production machinery no longer simply “processes” the product, but that the product communicates with the machinery to tell it exactly what to do. Connecting embedded system production technologies and smart production processes creates new technological age advantages, which will radically transform industry and production value chains and business models (e.g. “Smart Factory”).
5. Survey and results

Empirical research based on theoretical findings was performed from July 2013 until September 2014. The population of the survey was – 8 981 enterprises of Latvian manufacturing companies working in manufacturing industry. The number of respondents surveyed (368 surveyed online) compared to the number of companies reflected in the database made up 4.09% (5.00 confidence interval). During industrialisation factor analysis, the research authors constructed the questionnaire with the number of variables determined by the context of the research. Quantitative data processing was performed with SPSS program, descriptive and conclusive statistical methods in data processing were used. Research results revealed industrialisation diffusion problems for SME (use of industrialisation advantages). The calculation of the SME industrialisation diffusion is performed by using formula (1):

\[
\text{IndDistr} = \frac{\bar{R}}{\text{Impl}}
\]

\(\text{IndDistr}\) - the distribution assessment of industrialisation factors among SMEs in manufacturing industry;

\(\frac{\text{Impl}}{n} = \frac{\sum \text{impl}}{n}\) - the average evaluation of the industrialisation factors implementation by the company, using 6 point Likert scale;

\(\bar{R} = \frac{\sum R}{n}\) - the average role of the industrialisation factor for value added, using 6 point Likert scale.

The result of the companies’ industrialization factors’ significance is shown in Figure 5.

Based on results SMEs still highly evaluate industrialisation factors, but could not take full advantages of them. Exploiting economies of scale and transactional cost factors will significantly reduce operation cost and increase profit margin. Currently Latvian SMEs are exploiting operations management and flexible manufacturing system. In case of SMEs, associations and Industrial Parks could provide necessary transactional cost reduction.

![](image_url)
The authors conclude that implementation of industrialisation factors is insufficient to create high value added products for SMEs (30% - average industrialisation factors’ implementation by companies for top ten valued factors) Figure 5.

6. Conclusions

The discussed above results allow concluding that conventional industrialisation development is no longer dominant in modern economy. For the purposes of the modern industrialisation approach, information and knowledge-based perspectives are useful in understanding the structural changes associated with the industrialisation transition into post-industrialism. New relationships with customers, the integration of information and knowledge-based perspectives and organization development theory in dynamic environment to the context of industrialisation are the relevant and problematic issues of management science. The solution of them could expand the field of management research and could fill the gaps of scientific discussion on the topic.

In this paper, our main goal was to reveal the challenges for modern industrialisation concept concerning the post-industrial society approach. The authors use “superimposing” method to explain industrialisation transformation process to the modern post-industrial value creation process. The authors see it as the most appropriate method to integrate industrialisation factors into post-industrial society, in order to correspond to the economic transformation into post-industrial.

With the information age industrialization factors were “superimposed” to the information-processing system in the rationalisation and improvement work. The demand for knowledge-based resources and advance of modern ICT will exploit the Industry 4.0, newest strategic initiative focused on intangible assets. Traditional industrialization environment expected to transform into fourth industrial revolution advantages, across the entire value chain and the full product life cycle integrating into new environment.

Acknowledgments

The paper was supported by the project «The Development of Innovation and Entrepreneurship in Latvia in Compliance with the Smart Specialization Strategy» within the National Research Program 5.2. «Economic Transformation, Smart Growth, Governance and Legal Framework for the State and Society for Sustainable Development - a New Approach to the Creation of a Sustainable Learning Community (EKOSOC-LV)>>
